Abstract—Quantitative analysis of geometrical isomers of unsaturated esters and alcohols is facilitated with $Eu(fod)_3$. Commercial sorbic acid exists in the all-trans form, while sorbyl alcohol contains c. 10% of the cis-4,5 isomer.

NMR CHEMICAL shift reagents continue to find widening application in elucidating coupling constants and geometric configurations¹ of organic molecules. Esters,² alcohols and ketones³ give greatly simplified spectra with Eu(fod)₃ 1 at Eu/substrate concentrations c. 0·2 to 0·5. Recently Swern and Wineburg⁴ demonstrated the utility of 1 in elucidating possible branching in the structures of long chain fatty acids. We wish to report that 1 is a useful reagent for qualitative and quantitative estimations of isomer distributions in sorbate esters and sorbyl alcohol.

In a related study⁵ we wished to determine the isomer distribution of 2,4-hexadienoic (sorbic) acid obtained from various natural and commercial sources. Since acids decompose shift reagents,6 commercial sorbic acid (Aldrich) was treated with diazomethane. The resulting ester gave a complex, non-analyzable olefinic NMR pattern. Addition of 1 to CH₃CH=CHCH= CHCO2Me (2) gave a first-order spectrum at a c. 0.4 1/ester molar ratio, the spectrum showing six cleanly separated resonances consistent with the all-trans configuration: (OCH₃, s), (H_{α}, d, $J_{\alpha\beta} = 16$ Hz), (H_{β}, d of d, $J_{\beta\gamma} = 10$ Hz), (H_{γ}, d of d, $J_{\gamma\delta} = 15$ Hz), (H_{δ}, six lines, $J_{\delta-\text{CH}3} = 6$ Hz), (CH₃, d). The same spectrum was obtained sortion and configuration and the spectrum variety of the same spectrum variety of the acid, methanol and sulfuric acid. However, when ester prepared from sorboyl chloride and methanol was so analyzed, new multiplets appeared in the spectrum, indicating the presence of another isomer. A second OCH₃ singlet appeared upfield together with second upfield patterns for both H_{α} and H_{β} . These exhibited the same multiplicity and coupling constants as above. However, the H_{γ} and H_{δ} patterns still overlapped with those from all-trans isomer. The terminal CH_3 showed a new doublet downfield from the corresponding all-trans isomer doublet, with long range doublet splitting, in accord with H, and H, being cis. Integration showed a 17% concentration of the 2-trans-4-cis isomer.

The induced shift ratio concept elaborated by Swern and Wineburg⁴ is of utility in analyzing these data. The induced shift ratio Ξ is independent of shift reagent concentration, and depends only on the relative shifts of a particular proton H_{α} and a standard proton H_{α} in

Table 1. Induced shift ratios for all-trans (2a) and 2-trans-4-cis (2b) methyl sorbate a,b

| | H_{α} | OCH_3 | $\mathbf{H}_{\pmb{\beta}}$ | \mathbf{H}_{γ} | ${ m H}_{\pmb{\delta}}$ | C—CH ₃ |
|---|--------------|--------------|----------------------------|-----------------------|-------------------------|-------------------|
| $\frac{\delta_{\mathbf{b}}/\delta_{\mathbf{2a}}}{\Xi_{\mathbf{2a}}^{\mathbf{c}}}$ | 0·93 1·0 | 0·89 1·05 | 0·97 0·99 | 0·98 0·22 | 1·00 0·11 | 1·18 0·04 |
| Ξ2a ^d | 1.0 | 1 01 | 1.08 | 0.18 | 0.07 | 0.15 |

 a At 60 MHz, CCl₄ solution. bRelative to $H_\alpha=1\cdot 0.~^oAverage$ of 8 runs with Eu/ester molar ratio 0·03 to 0·4. dAt Eu/ester = 0·35.

As Ξ in long chain alcohols and esters is a function monotonically decreasing with increasing distance from the complexation site,⁴ it is of interest to note the inversion of $\Xi_{\rm H\delta}$ and $\Xi_{\rm C-CH3}$ in the isomers 2a and 2b. Examination of structure diagrams shows that H_{δ} and $C-CH_{3}$ exchange their spatial locations relative to the ester function as the 4,5-double bond inverts configuration.

Although the criteria of lanthanide induced shifts obeying a r^{-3} 'distance only' relationship has been substantially refuted,⁸ it is conceded that shift reagents will associate with substrates so as to minimize steric interaction, and that only molecules in which the substrate is forced (by steric constraints) to envelop the metal ion will be expected to show large variations of Φ in the pseudo-contact shift equation, $\Delta H/H = K(3\cos^2\Phi - 1)/r^3$. The noncyclic materials used in this study are expected to closely approximate the 'distance only' criterion of induced shift.

2-cis-4-trans-Hexadienoic acid is known to be an unstable, readily polymerizing compound⁵ and the all-cis isomer is unknown, hence Eu(fod)₃ spectra of these compounds were not obtained. Quantitative analysis of mixtures containing these isomers should be possible, as $\Xi_{\rm H\beta}$ and $\Xi_{\rm H\gamma}$ should behave as $\Xi_{\rm H\delta}$ and $\Xi_{\rm H_{\rm CCH_3}}$ did when the 4,5 double bond reversed configuration, moving the H_{β} and H_{γ} resonances to unobscured regions of the spectrum.

Although definite proof awaits further study, we speculate that the 4-cis-sorbate produced in the thionyl chloride mediated esterification is formed via a Diels-Alder reaction with SO₂, enolization and retro-Diels-Alder reaction sequence.

the same molecule, which in esters, alcohols and ketones is defined as the proton most proximate to the functional group. $\Xi_x = (\delta_{\rm Eu} - \delta_0)_x/(\delta_{\rm Eu} - \delta_0)_\alpha$, where $\delta_{\rm Eu}$ and δ_0 are respectively the chemical shifts with and without the presence of shift reagent. The induced shift ratios of the two sorbic acid isomers, together with the relative chemical shifts of the protons in the two isomers, are given in Table 1.

Commercial 2,4-hexadienol (Eastman) (3), treated with 1, gave a first-order 60 MHz spectrum at Eu/ ester = 0.4, which indicated a predominantly all-trans configuration: H^1 , d, $J_{12} = 5$; H^2 , t of d, $J_{23} = 14$; H^3 , d of d, $J_{34} = 10$; H^4 , d of d, $J_{45} = 14$; H^5 , q of d, $J_{56} = 5.5$; H^6 , d. The induced shift ratios Ξ : H^1 , 1.0; H^2 , 0.56; H^3 , 0.53; H^4 , 0.22; H^5 , 0.11; H^6 , 0.05; OH, 3.96 supported this conclusion. However, the H⁶ region of the spectrum showed a downfield second doublet with long range doublet splitting. The long range splitting7 and Ξ value of this doublet implied that it arose from the 4,5-cis isomer of sorboyl alcohol. From peak height measurement the concentration of 4,5-cis-2,4hexadienol in commercial sorbyl alcohol can be estimated as 10%.

Several other commercial materials were analyzed by this technique for geometric isomers, including 4-phenyl-3-buten-2-one and methyl cinnamate. These compounds all gave first-order spectra at Eu/substrate = 0.4 or less. The spectra indicated the presence of only the trans isomer. We estimate that the Eu(fod)₃ method

would detect the presence of c. 2% of a cis isomer. Further applications of shift reagents to structural problems are under investigation.
